## Discretization of a Random Field – a Multiobjective Algorithm Approach

Guang-Yih Sheu  
Chang-Jung Christian University  
Taiwan

### 1. Introduction

Discretization of a random field by the generalized polynomial chaos (GPC) begins with selecting a specific type of orthogonal polynomial (e.g. Legendre and Hermite polynomials) (e.g. Ghanem and Spanos, 1991). This selection of a type of orthogonal polynomial can be performed based on the reported experiences (e.g. Xiu and Karniadakis, 2003) or data revealing the distribution of a random field to be discretized. If such data or reported experiences are unavailable, a third way may be generating some pilot tests to study the performance of a specific type of orthogonal polynomial in discretizing this random field. This study tries to develop an evolutionary algorithm-based auxiliary tool for the implementation of such pilot tests. A similar tool (Allaix and Carbone, 2009), which is based on the single-objective evolutionary algorithm, had been developed for constructing the Karhunen-Loève (KL) representation of a random field. Both KL and GPC expansions are two of the popular random field discretization methods (Ghanem and Spanos, 1991). But, the KL expansion should be applied under a prerequisite of knowing the covariance matrix of a random field to be discretized (e.g. Ghanem and Spanos, 1991); while, the GPC expansions can be applied without similar prerequisites (e.g. Xiu and Karniadakis, 2003). Therefore, the development of an auxiliary tool for constructing a GPC representation of a random field would be necessary.

The succeeding research considers the derivation of an GPC representation of a random field as a multi-objective (MO) problem having two goals: (a) limiting the computational efforts spent in applying the resulting GPC representation; and (b) keeping the resulting GPC representation satisfying all accuracy standards (e.g. getting the sufficiently accurate prediction of statistical parameters of a random field). The former goal will be attained by limiting the highest order of polynomial term and total number of uncorrelated random variables used to construct a GPC representation; while the latter goal will be attained by minimizing multiple error estimators. Since there are multiple goals to be attained, a multiple objective evolutionary algorithm (MOEA) is required. Among all available MOEAs, the strength Pareto evolutionary algorithm II (SPEA 2) (Zitzler, et al., 2001) is chosen. The highest order of polynomial term and total number of uncorrelated random variables used to construct an GPC representation are considered as two parameters to be identified.

The remainder of this study is organized into four sections. In Sec. 2, the theoretical backgrounds of GPC expansions (e.g. Xiu and Karniadakis, 2003) are briefly reviewed. In Sec. 3, the SPEA 2 (Zitzler, et al., 2001) is used to construct a parameter identification procedure to identify the aforementioned highest order of orthogonal polynomial and total

number of uncorrelated random variables. Two examples are introduced to study the performance of the resulting works are tested in Sec. 4. The test results are used to give some discussion and conclusion in Sec. 5.

## 2. Generalized polynomial chaos expansion

### 2.1 Definition

The GPC (e.g. Xiu and Karniadakis, 2002) is a generalization of the classical Wiener's PC (polynomial chaos). This Wiener's PC is defined as the span of Hermite polynomials of a Gaussian process. A Cameron-Martin theorem states that the Wiener's PC can be used to approximate any functional in  $L_2(C)$  and converges in the  $L_2(C)$  sense in which  $C$  denotes the space of real functions, which are continuous over the interval  $[0, 1]$  and vanish at 0. The GPC further provides a mean of expanding second-order random fields having finite variance over a specific interval in terms of orthogonal polynomials. Most physical processes can be simulated by such second-order random fields. As compared to the Wiener's PC, the GPC has better performance in representing some specific types of non-Gaussian inputs.

Suppose  $\theta$  is an event in the probabilistic space, and  $u(\theta)$  is a continuous function of  $\theta$ . The GPC representation of  $u$  is equated by (e.g. Xiu and Karniadakis, 2002)

$$u = a_0 \psi_0(\xi_{i_0}) + \sum_{i_1=1}^{\infty} a_{i_1} \psi_1(\xi_{i_1}) + \sum_{i_1=1}^{\infty} \sum_{i_2=1}^{i_1} a_{i_1 i_2} \psi_2(\xi_{i_1}, \xi_{i_2}) \\ + \sum_{i_1=1}^{\infty} \sum_{i_2=1}^{i_1} \sum_{i_3=1}^{i_2} a_{i_1 i_2 i_3} \psi_3(\xi_{i_1}, \xi_{i_2}, \xi_{i_3}) + \dots \quad (1)$$

where  $a_0, a_{i_1}, a_{i_1 i_2}, \dots$  denote the coefficients to be determined and  $\psi_n, n = 0, 1, 2, \dots$  are the polynomial chaos (PC) of order  $n$  of multi-dimensional independent random variables  $\xi_{i_1}, \xi_{i_2}, \dots, \xi_{i_n}$  having zero mean and unit variance.

For the notational convenience, Eq. (1) is further modified to (e.g. Xiu and Karniadakis, 2002)

$$u = \sum_{i=0}^{\infty} U_i \Psi_i(\xi) \quad (2)$$

where  $\xi = (\xi_{i_1}, \xi_{i_2}, \dots, \xi_{i_n})$ ,  $\Psi_0 = 1$ , and  $U_0$  is set to the mean value of  $u$ . There is a one-to-one correspondence between  $\Psi_i$  and  $\psi_n$  and between  $a_0, a_{i_1}, a_{i_1 i_2}, \dots$  and  $U_i$ . For example, suppose  $u$  is as functions of  $\mathbf{x}$  and  $\xi = (\xi_{i_1}, \xi_{i_2})$ . The relationship between  $\Psi_i, i = 0-9$  and  $\psi_n, n = 0-3$  is given by

$$\begin{aligned} \Psi_0 &= \psi_0(\xi_{i_1})\psi_0(\xi_{i_2}) = 1, & \Psi_1 &= \psi_1(\xi_{i_1})\psi_0(\xi_{i_2}), & \Psi_2 &= \psi_0(\xi_{i_1})\psi_1(\xi_{i_2}) \\ \Psi_3 &= \psi_2(\xi_{i_1})\psi_0(\xi_{i_2}), & \Psi_4 &= \psi_1(\xi_{i_1})\psi_1(\xi_{i_2}), & \Psi_5 &= \psi_0(\xi_{i_1})\psi_2(\xi_{i_2}) \\ \Psi_6 &= \psi_3(\xi_{i_1})\psi_0(\xi_{i_2}), & \Psi_7 &= \psi_2(\xi_{i_1})\psi_1(\xi_{i_2}), & \Psi_8 &= \psi_1(\xi_{i_1})\psi_2(\xi_{i_2}) \\ \Psi_9 &= \psi_0(\xi_{i_1})\psi_3(\xi_{i_2}) \end{aligned} \quad (3)$$

In addition, because  $\Psi_i, i = 0-\infty$  and  $\psi_n, n = 0-\infty$  are orthogonal polynomials in terms of  $\xi$ , it can be obtained:

$$\langle \Psi_i, \Psi_j \rangle = \langle \Psi_i^2 \rangle \delta_{ij} \text{ and } \langle \psi_i, \psi_j \rangle = \langle \psi_i^2 \rangle \delta_{ij}, \quad \forall i, j = 0-\infty \quad (4)$$

where  $\delta_{ij}$  is the Kronecker delta (i.e.  $\delta_{ij} = 1$  if  $i = j$  and  $\delta_{ij} = 0$  if  $i \neq j$ ),  $\langle \cdot, \cdot \rangle$  is the ensemble average. If  $f$  and  $g$  are two orthogonal polynomials of  $\xi$ ,  $\langle \cdot, \cdot \rangle$  is computed by (Xiu and Karniadakis, 2002; Xiu and Karniadakis, 2003)

a. Continuous case (i.e.  $\xi_{i_1}, \xi_{i_2} \dots$  and  $\xi_{i_n}$  vary continuously over the probabilistic space):

$$\langle f(\xi), g(\xi) \rangle = \int \int \dots \int f(\xi) g(\xi) w(\xi_{i_1}) w(\xi_{i_2}) \dots w(\xi_{i_n}) d\xi_{i_1} d\xi_{i_2} \dots d\xi_{i_n} \tag{5a}$$

b. Discrete case (i.e.  $\xi_{i_1}, \xi_{i_2} \dots$  and  $\xi_{i_n}$  vary discretely over the probabilistic space):

$$\langle f(\xi), g(\xi) \rangle = \sum_{\xi_{i_1}} \sum_{\xi_{i_2}} \dots \sum_{\xi_{i_n}} f(\xi) g(\xi) w(\xi_{i_1}) \dots w(\xi_{i_n}) \tag{5b}$$

where  $w(\xi_{i_1}), w(\xi_{i_2}) \dots w(\xi_{i_n})$  represent the weighting functions.

Equation (4) can be used to get  $U_i, i = 0-\infty$ . Multiplying Eq. (2) with  $\Psi_i, i = 0-\infty$  and simplifying the resulting equations according to Eq. (5a) or (5b) give

$$U_i = \frac{\langle u \Psi_i \rangle}{\langle \Psi_i^2 \rangle}, \quad \forall i = 0-\infty \tag{6}$$

In practice, not all  $U_i$  are computed. Eq. (2) can be truncated as follows

$$u = \sum_{i=0}^M U_i \Psi_i(\xi) \tag{7}$$

where  $M$  is  $\frac{(n+P)!}{n!P!} - 1$ ,  $n$  represents the total number of uncorrelated random variables, and  $P$  is the highest order of polynomial term used to equate  $\Psi_i$ .

Tables 1-2 (e.g. Xiu and Karniadakis, 2002) list available choices of orthogonal polynomials and corresponding statistical distributions and weighting functions to generate  $\Psi_i, i = 0-\infty, \xi_{i_1}, \xi_{i_2} \dots \xi_{i_n}$ , and  $w(\xi_{i_1}), w(\xi_{i_2}) \dots w(\xi_{i_n})$ ; respectively.

Distribution	Polynomial	$w(\xi)$	Interval
Gaussian gamma beta uniform	Hermite polynomial $H_n(x)$	$\exp(-\xi^2)$	$(-\infty, \infty)$
	Laguerre polynomial $L_n(x)$	$\exp(-\xi)$	$[0, \infty]$
	Jacobi polynomial $G_n(p, q, x)$	$(1-\xi)^{p-q} \xi^{q-1}$	$[a, b]$
	Legendre polynomial $P_n(x)$	1	$[a, b]$

Table 1. Polynomials, weighting functions, and statistical distributions for generating an GPC expansion (Continuous case) (e.g. Xiu and Karniadakis, 2002)

Distribution	Polynomial	$w(\xi)$	Interval
Poisson binomial negative binomial hypergeometric	Charlier polynomial $C(x, \lambda)$	$\exp(-\lambda) \lambda^\xi / \xi!$	$\{0, 1, 2, \dots\}$
	Krawtchouk polynomial $K_n(x, p, N)$	$N! p^\xi (1-p)^{N-\xi} / [\xi!(N-\xi)!]$	$\{0, 1, \dots, N\}$
	Meixner polynomial $M_n(x, \beta, c)$	$(\beta)_\xi (1-c)^\beta c^\xi / \xi!$	$\{0, 1, 2, \dots\}$
	Hahn polynomial $Q_n(x, \alpha, \beta, N)$	$(\alpha+\xi)!(\beta+N-\xi)! / [\xi!\alpha!(N-\xi)!\beta!]$	$\{0, 1, \dots, N\}$

Table 2. Polynomials, weighting functions, and statistical distributions for generating an GPC expansion (Discrete case) (e.g. Xiu and Karniadakis, 2002)

Furthermore, some references (e.g. Xiu and Karniadakis, 2002; Xiu and Karniadakis, 2003) had summarized useful properties about those orthogonal polynomials listed in Tables 1-2. Interested readers may refer to these papers and these properties are not repeatedly listed here.

## 2.2 Discretization error estimator

Discretizing  $u$  by Eq. (7) causes some discretization errors. These discretization errors can be quantified by some error estimators. For example, the exact value of standard deviation of  $u$  (or other statistical parameters) and the one provided by Eq. (7) can be used to equate an error estimator. However, the exact value of standard deviation of  $u$  may be unavailable or difficult to be obtained. At such a situation, a Monte Carlo simulation (MCS) is required. This MCS is performed by first generating some samples of  $u$ . The standard deviation of resulting samples of  $u$  is then computed. It had been concluded (e.g. Ghanem and Spanos, 1991) that the standard deviation of  $u$  provided by an MCS will approach its exact value, if a sufficiently large amount of samples have been generated to implement the MCS. Thus, statistical parameters computed by an MCS, which is completed using a large amount of samples of  $u$ , can be used to understand the accuracy of Eq. (7).

For simplicity, this study defines two types of error estimators to quantify the discretization errors. The values of these error estimators are kept within an acceptable range when constructing a GPC representation of a random field. The first type of error estimator is equated to quantify the error  $\varepsilon_1$  caused by truncating Eq. (2) to derive Eq. (7). At a specific  $\xi$ ,  $\varepsilon_1$  is defined by (Field and Grigoriu, 2004)

$$\varepsilon_1 = \frac{1}{u_{ex}} \sum_{i=M+1}^{\infty} U_i \Psi_i = \frac{1}{u_{ex}} \left( u_{ex} - \sum_{i=0}^M U_i \Psi_i \right) = 1 - \frac{1}{u_{ex}} \sum_{i=0}^M U_i \Psi_i \quad (8)$$

where the subscript  $ex$  denotes the exact value.

The second type of error estimator is equated to quantify the errors between the exact value of standard deviation of  $u$  and the one computed based on Eq. (7). Suppose  $\sigma_{ex}$  and  $\sigma_{GPC}$  denote the exact value of standard deviation of  $u$  and the one provided by Eq. (7); respectively. The latter  $\sigma_{GPC}$  is computed by (Ghanem and Spanos, 1991)

$$\sigma_{GPC} = \sqrt{\sum_{i=1}^M U_i^2 \langle \Psi_i^2 \rangle} \quad (9)$$

Based on Eq. (9), the error  $\varepsilon_2$  between  $\sigma_{ex}$  and  $\sigma_{GPC}$  is defined by

$$\varepsilon_2 = \frac{1}{\sigma_{ex}} \left[ \sigma_{ex} - \sqrt{\sum_{i=1}^M U_i^2 \langle \Psi_i^2 \rangle} \right] = 1 - \frac{1}{\sigma_{ex}} \sqrt{\sum_{i=1}^M U_i^2 \langle \Psi_i^2 \rangle} \quad (10)$$

If  $\sigma_{ex}$  is unavailable or difficult to be obtained,  $\sigma_{MCS}$  is substituted for it where the subscript MCS denotes the Monte Carlo simulation.

Equations (8) and (10) will be used to define the objective functions in the next section.

## 3. Parameter identification procedure

As stated in Sec. 1, this study considers the derivation of an GPC representation of a random field as an MO problem and applies the SPEA2 (Zitzler et al., 2001) to solve this MO

problem. Mathematically, an MO problem is defined by (Tan, et al., 2005) finding a set of vector,  $\mathbf{P}$  such that

$$\min_{\Theta \in \Phi} F(\Theta) \quad \Theta \in \mathbb{R}^N \quad (10)$$

where  $\Theta = \{\theta_1, \theta_2, \dots, \theta_N\}$  is an  $N$ -dimensional vector having  $N$  parameters,  $\Phi$  defines a feasible set of  $\Theta$ , and  $F = \{f_1, f_2, \dots, f_m\}$  is an objective vector with  $m$  objective functions  $f_i$  ( $i = 1$  to  $m$ ) to be minimized.

For the succeeding research, suppose the mean value and  $\sigma$  of a random field to be discretized have been known or computed by an MCS. It is intended to identify  $n$  and  $P$  for constructing the GPC representation of this random field; thus,  $\Theta$  is equal to  $\{n, P\}$ . Meanwhile, the goals are (a) limiting the computational efforts spent in applying the resulting GPC representation; (b) keeping the accuracy of resulting GPC representation satisfying all accuracy standards. The former goal can be attained by choosing  $n$  and  $P$  within an acceptable range; while, this study attains the latter goal by minimizing the next three objective functions  $f_i$ ,  $i = 1-3$ :

$$\begin{aligned} f_1 &= \varepsilon_1(\xi_{i_1} = \xi_{i_2} = \dots = \xi_{i_n} = \xi_a) - S_1 \\ f_2 &= \varepsilon_1(\xi_{i_1} = \xi_{i_2} = \dots = \xi_{i_n} = \xi_b) - S_2 \\ f_3 &= \varepsilon_2 - S_3 \end{aligned} \quad (11)$$

where  $\xi_a$  and  $\xi_b$  denote two specific values of  $\xi$  and  $S_i$ ,  $i = 1-3$  are three constants.

Based on those concepts (Tan, et al., 2005), which are frequently mentioned in solving an MO problem, Sec. 3.1 lists the general steps to identify  $n$  and  $P$ . Secs. 3.2-3.3 explains the details of specific steps.

### 3.1 General structure

The identification of  $n$  and  $P$  is performed by next six steps:

- Initially, generating  $2N$  random numbers for creating a population  $\Theta_t$  (the subscript  $t$  denotes the generation number) containing  $N$  sets of candidate values of  $n$  and  $P$ . Since  $n$  and  $P$  should be integers, each random number is rounded to its nearest integer for producing a candidate  $n$  or  $P$  value. Besides, create an empty archive  $\Xi_t$  for storing the resulting Pareto optimal set. Limit the maximum size of  $\Xi_t$  to a number  $N_{\max}$ .
- Compute the fitness value of each individual of  $\Theta_t \cup \Xi_t$ . This fitness value is defined as the sum of the number of individuals dominating an individual and the density assessment at this individual in an objective space. The density assessment is used to speed up the convergence of Pareto optimal set until it contains only nondominated individuals. Sec. 3.2 further explains the computation of fitness values of an individual.
- Generate a temporary Pareto optimal set as follows (Tan, et al., 2005 and Zitzler, et al., 2001): Nondominated individuals of  $\Theta_t \cup \Xi_t$  are first copied to  $\Xi_{t+1}$ . If there are less than  $N_{\max}$  individuals in the resulting  $\Xi_{t+1}$ , sort dominated individuals of  $\Theta_t \cup \Xi_t$  in an ascending order by their fitness values. Fill  $\Xi_{t+1}$  with first  $(N_{\max} - |\Xi_{t+1}|)$  dominated individuals ( $|\Xi_{t+1}|$  is the size of  $\Xi_{t+1}$ ). If there are more than  $N_{\max}$  individuals in the resulting  $\Xi_{t+1}$ , sort  $\Xi_{t+1}$  in a descending order by the distance of each individual to its  $k$ -th nearest neighbor. Then, remove last  $(|\Xi_{t+1}| - N_{\max})$  individuals from the sorted  $\Xi_{t+1}$ . A reference book (Tan, et al., 2005) gives the pseudo-codes to implement this step.

- d. Test whether a stopping criterion is satisfied. For example, it can stop when a maximum generation number is reached. If the stopping criterion is satisfied, the final Pareto optimal set is  $\Xi_{t+1}$ . Then, go to Step (f). Otherwise, execute the tournament selection, crossover, and mutation genetic operators to fill  $\Theta_{t+1}$  with P offspring of individuals of  $\Xi_{t+1}$ . The implementation of these genetic operators is explained in Sec. 3.3.
- e. Increment the generation number t. Repeat Steps (a) to (d).
- f. Select manually the final values of n and P from  $\Xi_{t+1}$ .

### 3.2 Fitness assignment

Continuing Step (b) of Sec. 3.1, suppose the fitness value of each individual of  $\Theta_t \cup \Xi_t$  to be computed. The fitness value  $F_i$  of an i-th individual is obtained by (Zitzler, et al., 2001)

$$F_i = R_i + D_i \quad (12)$$

where  $R_i$  is the raw fitness value defined based on the total number of individuals dominating the i-th individual and  $D_i$  denotes the density assessment at the i-th individual in an objective space.

The total number of individuals dominating an i-th individual is represented by a strength value  $S_i$  expressed in the form as

$$S_i = |\{j \mid j \in \Theta_t \cup \Xi_t \wedge i \succ j\}| \quad (13)$$

where j denotes the j-th individual,  $|\cdot|$  denotes the cardinality of a set, and  $\succ$  denotes the Pareto dominance. Based on Eq. (13),  $R_i$  is defined by

$$R_i = \sum_{j \in \Theta_t \cup \Xi_t \wedge j \succ i} S_j \quad (14)$$

However, Eq. (14) may fail when most individuals do not dominate each other. Therefore, Eq. (12) includes  $D_i$  and it is computed by the distance  $d_i^k$  to its k-th nearest neighbor. The method for calculating  $d_i^k$  is as follows: First, calculate the distances of an i-th individual to all other j-th individuals of  $\Theta_t \cup \Xi_t$ . Thus

$$d_{ij} = \sqrt{\sum_{L=1}^3 (f_{L,i} - f_{L,j})^2} \quad (15)$$

where the subscripts i and j denote the i-th and j-th individual; respectively. The resulting  $d_{ij}$  are then stored in a list. Sort this list and  $d_i^k$  is the k-th element of sorted list. The resulting  $d_i^k$  is used to define  $D_i$  as follows:

$$D_i = \frac{1}{d_i^k + 1} \quad (16)$$

in which 1 in the denominator is to ensure Eq. (16) is less than 1.

### 3.3 Genetic operators

The tournament selection, crossover, and mutation operators are applied to produce the offspring of those random numbers generated for getting candidate n and P values. Those random numbers should be coded into chromosomes before applying those genetic operators (Tan, et al., 2005).

- In the tournament selection operation, two chromosomes are randomly selected. Discard the chromosome dominated by the other one. If else, two chromosomes are all conserved. Consider a population  $\Xi$  as an example. The tournament selection operation will repeat  $|\Xi|$  times ( $|\Xi|$  denotes the size of  $\Xi$ ).
- In the crossover operation, the crossover probability  $p_c$  is first defined. Two chromosomes, which have survived from the tournament selection operation, are chosen as the parents for producing the offspring. The offspring are generated by combining parts of the chromosomes contributed by each parent. Continuing using  $\Xi$  in Step (a), the crossover operation will repeat until  $\Xi$  is recovered to its original size. Figure 1(a) further illustrates this crossover operation in which chromosomes are represented by binary strings.
- In the mutation operation, the mutation probability  $p_m$  is first set. A chromosome, which has survived from the tournament selection operation, is randomly selected. The structure of it is randomly changed to produce a new chromosome. Continuing using  $\Xi$  in Steps (a)-(b), the crossover operation will repeat  $\frac{|\Xi|}{2}$  times. Figure 1(b) illustrates this mutation operator in which the chromosome to be mutated is also represented by a binary string.

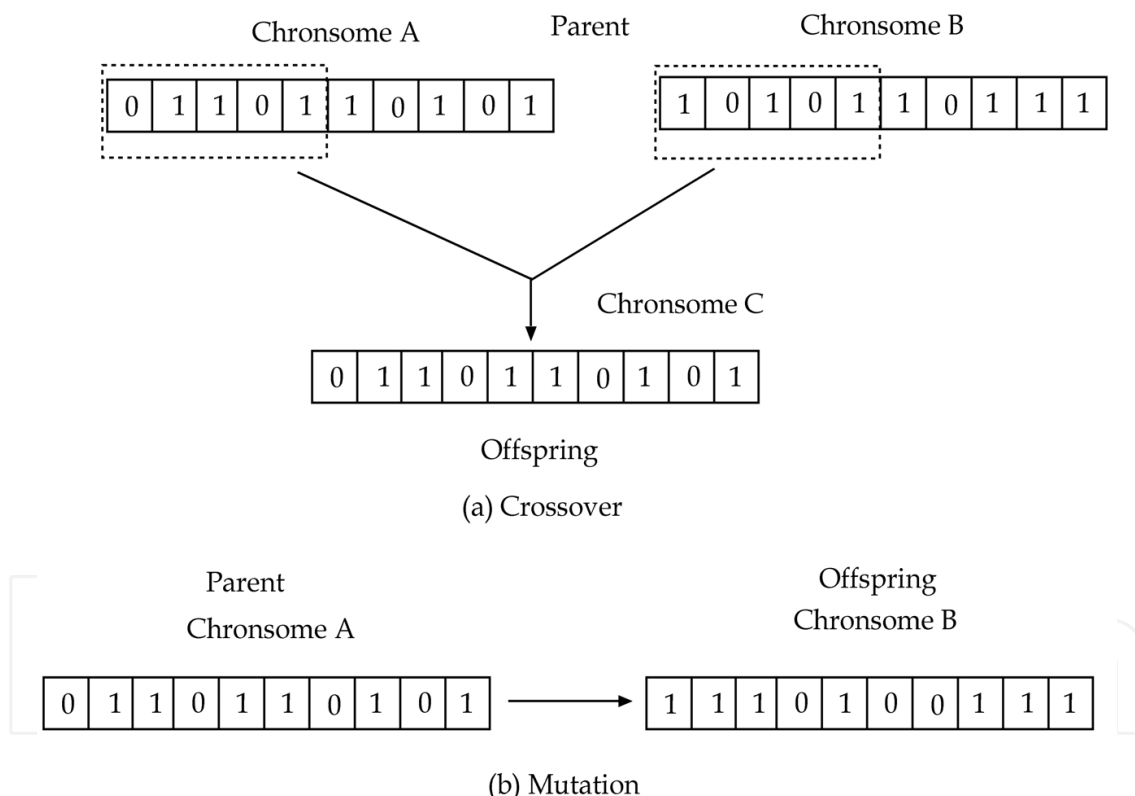

Fig. 1. Illustration of two genetic operators: (a) Crossover; (b) Mutation

## 4. Results

Two examples are generated to study the performance of resulting works in Sec. 3. The first example is discretizing a random field  $u$  varying with a lognormal distribution:

$$u = 1 + \log \left( 0.12^2 \sum_{i=1}^n \xi_i \right) \quad (17)$$

where  $-1 \leq \xi_i$  ( $i = 1-2$ )  $\leq 1$  denotes  $n$  random numbers. By implementing an MCS using  $10^5$  samples of  $u$ , the mean  $\mu_u$  and  $\sigma_u$  of  $u$  are calculated by 2 and 0.12; respectively. A GPC representation of  $u$  is constructed with satisfying the following accuracy standard:

$$S_j = 10\%; \quad j = 1-3 \quad (18)$$

Essential parameters for identifying  $n$  and  $P$  are set by

- Find  $n$  and  $P$  within the range  $1 \leq n \leq 3$  and  $1 \leq P \leq 10$ .
- Set  $\xi_a = 1$  and  $\xi_b = -1.0$ .
- Set temporarily  $p_c$  and  $p_m$  are all equal to 1 and  $N_{\max}$  is 100. Study subsequently the convergence of  $f_i$ ,  $i = 1-3$  with respect to different  $p_c$  and  $p_m$  values.
- Set  $N = 100$  in producing candidate  $n$  and  $P$  values. (That is, total 200 random numbers are generated to produce candidate  $n$  and  $P$  values). Besides, generate 100 generations of candidate  $n$  and  $P$  values.
- Following temporarily Table 1 (e.g. Xiu and Karniadakis, 2002), apply the Hermite PC to construct an GPC representation of  $u$ . Introduce subsequently a different type of the GPC (e.g. the Legendre PC) to equate another GPC representation of  $u$  and compare the accuracy of two different GPC representations of  $u$ .

Figures 2 shows the convergence of  $f_i$ ,  $i = 1-3$ . The diversity of 1st and 100th generations of random numbers for generating candidate  $n$  and  $P$  values is shown in Fig. 3. Note that less than 100 ( $= N$ ) points are drawn in Fig. 2, since candidate  $n$  and  $P$  values are gotten by rounding some random numbers to their nearest integers.

Sorting the data of  $f_i$ ,  $i = 1-3$  depicted in Figs. 2-3 finds that the minimization of  $f_3$  and  $f_i$ ,  $i = 1-2$  cannot be simultaneously attained. For example, if  $n$  and  $P$  are chosen to minimize  $f_3$  ( $= 0.00319$ ), the corresponding  $f_i$ ,  $i = 1-2$  ( $f_1 = 0.0012$ ;  $f_2 = 0.0082$ ) are not equal to their minimum values ( $f_{1,\min} = 0.00079$  and  $f_{2,\min} = 0.0001$  (the subscript min denotes the minimum value)). In addition, examining Figs. 2-3 indicates that there may be two choices of final values of  $n$  and  $P$ . As listed in Table 3, if  $n$  and  $P$  are equal to 2 and 6; respectively,  $f_3$  is minimized but  $f_i$ ,  $i =$

Fig. 2. Convergence of  $f_i$ ,  $i = 1-3$  (Using the Hermite PC, Lognormal distribution)

Fig. 3. Diversity of random numbers for generating candidate n and P values (Using the Hermite PC, Lognormal distribution)

1-2 are not minimized. Meanwhile, if n and P are equal to 1 and 10;respectively,  $f_i, i = 1-2$  are minimized but  $f_3$  is not minimized. If only one set of final values of n and P is forced to be left, this study prefers the former set. Getting a sufficiently accurate predicted standard deviation is more important.

n	P	M	$f_1$	$f_2$	$f_3$
2	6	28	0.0012	0.0082	0.00319
1	10	10	0.0427	0.0019	0.257

Table 3. Two different choices of final values of n and P (Using the Hermite PC, Lognormal distribution)

Fig. 4. Convergence of  $f_i, i = 1-3$  (Using the Legendre PC, Lognormal distribution)

One may suspect that  $f_3$  can be further minimized, if  $u$  is represented by another type of the GPC. As a test, Fig. 2 is modified by substituting the Legendre PC for the Hermite PC to re-discretize  $u$ . Fig. 4 depicts the convergence of resulting  $f_i$ ,  $i = 1-3$ .

It seems to be difficult to compare  $f_3$  values provided by the Legendre PC-based and Hermite PC-based representations of  $u$  by simply observing Figs. 2 and 4. Therefore, another set of  $n$  and  $P$  values, which minimize  $f_3$ , are chosen from the data for depicting Fig. 4. Table 4 lists the resulting  $n$  and  $P$  values.

$n$	$P$	$M$	$f_1$	$f_2$	$f_3$
3	2	10	0.0022	0.0778	0.08811

Table 4. Final values of  $n$  and  $P$  (Using the Legendre PC, Lognormal distribution)

Comparing Tables 3 and 4, this study suggests that a random field varying with a lognormal distribution is better represented by the Hermite PC. If the Legendre PC-based representation of  $u$  is applied,  $f_3$  is not further minimized. In other words, the accuracy of predicted  $\sigma_u$  is not further improved, if the Legendre PC-based representation of  $u$  is used. The second example is representing another random field  $v$  varying with a uniform distribution:

$$v = 1 + 0.12^2 \sum_{i=1}^n \xi_i \tag{19}$$

where  $-1 \leq \xi_i$  ( $i = 1-2$ )  $\leq 1$  still denote  $n$  random variables. Another MCS using  $10^5$  samples of  $v$  is performed. The mean value  $\mu_v$  and standard deviation  $\sigma_v$  of  $v$  are 1 and 0.12; respectively. Following Table 1 (e.g. Xiu and Karniadakis, 2002), the Legendre PC is applied to discretize  $v$ . With fixing other essential parameters for sketching Figs. 2-4, Fig. 5 shows the convergence of  $f_i$ ,  $i = 1-3$ . The diversity of 1st and 100th generations of random numbers for generating candidate  $n$  and  $P$  values is shown in Fig. 6.

Fig. 5. Convergence of  $f_i$ ,  $i = 1-3$  (Using the Legendre PC, Uniform distribution)

Fig. 6. Diversity of random numbers for generating candidate n and P values (Using the Legendre PC, Uniform distribution)

Sorting the data of  $f_i, i = 1-3$  depicted in Figs. 5-6 still finds that the minization of  $f_3$  and  $f_i, i = 1-2$  cannot be simultaneously attained. If n and P are chosen to minimize  $f_3$  ( $= 0.02635$ ), the corresponding  $f_i, i = 1-2$  ( $f_1 = 0.1363; f_2 = 0.1934$ ) are not equal to their minimum values ( $f_{1,min} = 0.0103$  and  $f_{2,min} = 0.0266$ ). Also examining Figs. 5-6 finds two choices of final values of n and P. Table 5 lists these two sets of final values of n and P. If n and P are equal to 3 and 10; respectively,  $f_3$  is minimized but  $f_i, i = 1-2$  are not minimized. Meanwhile, if n and P are equal to 2 and 8; respectively,  $f_i, i = 1-2$  are minimized but  $f_3$  is not minimized. This study still prefers the former set, although more computational efforts are required in applying this set of n and P values.

n	P	M	$f_1$	$f_2$	$f_3$
3	10	286	0.1363	0.1934	0.0264
2	8	45	0.0103	0.0266	0.1422

Table 5. Two different choices of final values of n and P (Using the Legendre PC, Uniform distribution)

Furthermore, similarly manipulating Fig. 4, the Hermite PC is substituted for the Legendre PC to re-discretize v and the convergence of corresponding  $f_i, i = 1-3$  is depicted in Fig. 7. Then, a set of n and P values, which minimize  $f_3$ , is chosen from the data for drawing Fig. 7. Table 6 lists the resulting n and P values.

If it is desired that the GPC representation of v should be as accurate as possible, Tables 5-6 confirms the reported conclusion (e.g. Xiu and Karniadakis, 2002) that a random field varying with a uniform distribution is better represented by the Legendre PC. Comparing Tables 5-6 indicates that the application of Hermite PC-based representation of v gives a less accurate predicted  $\sigma_v$ . However, if the computational efforts spent in applying a set of n and P values is the major concern, n = 2 and P = 10 may be used. The corresponding  $f_3$  value is not too worse.

Fig. 7. Convergence of  $f_i, i = 1-3$  (Using the Hermite PC, Uniform distribution)

n	P	M	$f_1$	$f_2$	$f_3$
2	10	66	0.053	0.027	0.066

Table 4. Final values of n and P (Using the Hermite PC, Uniform distribution)

Before closing this section, the effects of changing  $p_c$  and  $p_m$  on the determination of n and P values are studied. As an illustration, Figs. 3-4 are modified by changing  $p_c = p_m = 1.0$  to  $p_c = p_m = 0.9$ . Figs. 8-9 depict the convergence of  $f_i, i = 1-3$  and diversity of 1st and 100th generations of random numbers for producing candidate n and P values.

Fig. 8. Convergence of  $f_i, i = 1-3$  with  $p_c = p_m = 0.9$  (Using the Hermite PC, Lognormal distribution)

Fig. 9. Diversity of random numbers for generating candidate n and P values with  $p_c = p_m = 0.9$  (Using the Hermite PC, Lognormal distribution)

Observing Figs. 8-9 finds that the decrease of  $p_c$  and  $p_m$  affects insignificantly the convergence of  $f_i$ ,  $i = 1-3$  but diversifies the random numbers for generating candidate n and P values.

## 5. Discussion and conclusion

This study applies the SPEA2 (Zitzler, et al., 2001) to develop an auxiliary tool for identifying n and P values, which are two essential parameters for constructing a GPC representation of a random field. In Sec. 4, the proposed tool is tested to identify n and P for constructing GPC representations of two random fields varying with the lognormal and uniform distributions; respectively. The test results illustrate that an MOEA can be a good tool for constructing a sufficiently accurate GPC representation of a random field, irrespective of how many accuracy standards should be satisfied. Besides, the resulting GPC representation can be applied with keeping computational costs as few as possible.

In addition, Sec. 4 demonstrates the need of generating some pilot tests for studying the performance of GPCs in discretizing a random field before choosing one type of the GPC to discretize this random field. Such pilot tests can be quickly implemented by applying an MOEA. Tables 5-6 and Figs 5 and 7 demonstrate that the Hermite PC may be used to discretize a random field varying with a uniform distribution, if it can be sacrificed some accuracy of predicted statistical parameters (e.g. the standard deviation) of this random field.

Nevertheless, a disadvantage should be mentioned:  $\Psi_i$ ,  $i = 0-M$  may be difficult to be equated in case of  $n > 3$ . Although much computational efforts will be spent,  $n > 3$  may give more accurate GPC representation of a random field. Fortunately, consulting with some references (e.g. Field, 2004) finds that  $1 \leq n \leq 3$  seems to be enough to generate sufficiently accurate GPC representations of random fields.

As a conclusion, an MOEA can be an efficient auxiliary tool for constructing an GPC representation of a random field satisfying multiple accuracy standards. Only  $\Psi_i$ ,  $i = 0-M$  at  $n > 3$  may be complementally derived in the future.

Evolutionary algorithms are successively applied to wide optimization problems in the engineering, marketing, operations research, and social science, such as include scheduling, genetics, material selection, structural design and so on. Apart from mathematical optimization problems, evolutionary algorithms have also been used as an experimental framework within biological evolution and natural selection in the field of artificial life.
