Numerical Schemes for Fractional Ordinary Differential Equations

Weihoa Deng and Can Li

*School of Mathematics and Statistics, Lanzhou University, Lanzhou
People's Republic of China*

1. Introduction

Fractional calculus, which has almost the same history as classic calculus, did not attract enough attention for a long time. However, in recent decades, fractional calculus and fractional differential equations become more and more popular because of its powerful potential applications. A large number of new differential equations (models) that involve fractional calculus are developed. These models have been applied successfully, e.g., in mechanics (theory of viscoelasticity), biology (modelling of polymers and proteins), chemistry (modelling the anomalous diffusion behavior of Brownian particles), electrical engineering (electromagnetic waves) etc (Bouchaud & Georges, 1990; Hilfer, 2000; Kirchner et al., 2000; Metzler & Klafter, 2000; Zaslavsky, 2002; Mainrdis, 2008). Meanwhile, some rich fractional dynamical behavior which reflect the inherent nature of realistic physical systems are observed. In short, fractional calculus and fractional differential equations have played more and more important role in almost all the scientific fields. One of the most important fractional models is the following initial value problem

$$D_*^\alpha y(t) = f(t, y(t)), \quad y^{(k)}(x_0) = y_0^{(k)}, \quad k = 0, 1, \dots, [\alpha] - 1, \quad (1)$$

where $\alpha \in (0, \infty)$, $y_0^{(k)}$ can be any real numbers, and D_*^α denotes the fractional derivative in the Caputo sense, defined by

$$D_*^\alpha y(t) = J^{n-\alpha} D^n y(t) = \frac{1}{\Gamma(n-\alpha)} \int_0^t \frac{y^{(n)}(\tau)}{(t-\tau)^{1+\alpha-n}} d\tau, \quad (2)$$

here $n := [\alpha]$ is the smallest integer not less than α , $y^{(n)}(x)$ is the classical n th-order derivative of $y(x)$ and for $\mu > 0$, J^μ is the μ -order Riemann-Liouville integral operator expressed as follows

$$J^\mu y(t) = \frac{1}{\Gamma(\mu)} \int_0^t \frac{y(\tau)}{(t-\tau)^{1-\mu}} d\tau.$$

The use of Caputo derivative in above equation is partly because of the convenience to specify the initial conditions. Since the initial conditions are expressed in terms of values of the unknown function and its integer-order derivatives which have clear physical meaning (Podlubny, 1999; 2002). However, from pure mathematical viewpoint, the Riemann-Liouville derivative is more welcome and many earlier research papers use it instead of Caputo derivative (Podlubny, 1999). In general, specifying some additional conditions is necessary

to make sure the discussed equation has a unique solution. These additional conditions, in many situations, describe some properties of the solution at the initial time (Heymans & Podlubny, 2005), the fractional derivative does not have convenient used physical meaning (there are already some progress in the geometric and the physical interpretation of the fractional calculus (Podlubny, 2002) and the physical interpretation of the initial conditions in terms of the Riemann-Liouville fractional derivatives of the unknown function has also been discussed in (Podlubny, 2002)).

Just like the classic calculus and differential equations, the theories of fractional differentials, integrals and differential equations have been developing. With the development of the theories of fractional calculus, many research monographs are published, e.g., (Oldham & Spanier, 1974; Podlubny, 1999; Samko et al., 1993). In the literatures, several analytical methodologies, such as, Laplace transform, Mellin transform, Fourier transform, are restored to obtain the analytical solutions of the fractional equations by many authors (Metzler & Klafter, 2000; Podlubny, 1999; Samko et al., 1993; Zaslavsky, 2002; Mainrdis, 2008), however, similar to treating classical differential equations, they can mainly deal with linear fractional differential equation with constant coefficients. Usually, for nonlinear systems these techniques do not work. So in many cases the more reasonable option is to find its numerical solution. As is well known, the difficulty of solving fractional differential equations is essentially because fractional calculus are non-local operators. This non-local property means that the next state of a system not only depends on its current state but also on its historical states starting from the initial time. This property is closer to reality and is the main reason why fractional calculus has become more and more useful and popular. In other words, this non-local property is good for modeling reality, but a challenge for numerical computations. Much effort has been devoted during the recent years to the numerical investigations of fractional calculus and fractional dynamics of (1) (Lubich, 1985; 1986; Podlubny, 1999). More recently, Diethelm et al successfully presented the numerical approximation of (1) using Adams-type predictor-corrector approach (Diethelm & Ford, 2002a) and the detailed error analysis of this method was given in (Diethelm et al., 2004). The convergent order of Diethelm's predictor-corrector approach was proved to be $\min(2, 1 + \alpha)$ (Diethelm et al., 2004). Because of the non-local property of the fractional derivatives, the arithmetic complexity of their algorithm with step size h is $O(h^{-2})$, whereas a comparable algorithm for a classical initial value problem only gives rise to $O(h^{-1})$. To improve the accuracy and reduce the arithmetic complexity, some techniques such as the Richardson extrapolation, short memory principle and corresponding mixed numerical schemes are developed. In (Deng, 2007a), we present an improved version of the predictor-corrector algorithm with the accuracy increased to $\min(2, 1 + 2\alpha)$ and half of the computational cost is reduced comparing to the original one in (Diethelm et al., 2004). Furthermore, we apprehend the short memory principle from a new viewpoint (Deng, 2007b); after using the nested meshes presented in (Ford & Simpson, 2001) and combining the short memory principle and the predictor-corrector approach, we minimize the computational complexity to $O(h^{-1} \log(h^{-1}))$ at preserving the order of accuracy 2.

This chapter briefly reviews the recent development of the predictor-corrector approach for fractional dynamic systems. The plan of this chapter is as follows. In Section 2, we briefly discuss the short memory principle and the nested meshes. In Section 3, the predictor-corrector schemes and its improved versions are presented, meanwhile the convergent order and arithmetic complexity are also proposed. In Section 4, we provide two

numerical examples to illustrate the performance of our numerical schemes. Conclusions are given in the last section.

2. Short memory principle

We can see that the fractional derivative (2) is an operator depending on the past states of the process $y(t)$ (see Fig 1). However, for $t \gg 0$ and $0 < \alpha < 1$, the behavior of $y(t)$ far

Fig. 1. The fractional derivative operating on the "past" of $y(t)$ (the red part).

from upper terminal suggests that the original fractional derivative can possibly be replaced by the fractional derivative with a moving lower terminal (Podlubny, 1999). This means that the history of the process $y(t)$ can be approached only over a fixed period of recent history. Inspired by this kind of idea, Podlubny in (Podlubny, 1999) introduces a *fixed integral length memory principle* for Riemann-Liouville derivative (see Fig 2). He shows that the truncation

Fig. 2. The "short-memory" principle with "fixed memory length" $L(< t)$, where ${}_0D_t^\alpha$ denote the Riemann-Liouville derivative operator.

error gives $E < ML^{-\alpha}/\Gamma(1-\alpha)$ with a fixed integral length L . To accelerate the computation without significant loss of accuracy, in (Ford & Simpson, 2001) Ford and Simpson present a *short-memory principle* for Caputo derivative. In (Deng, 2007b) we apprehend the short memory principle from a new viewpoint, and then it is closer to reality and extends the effective range of short memory principle from $\alpha \in (0,1)$ to $\alpha \in (0,2)$. In view of the scaling property of fractional integral, the nested meshes are possibly used. And the *nested meshes* can be produced by splitting the integral interval $[0, t_n]$ into

$$[0, t_n] = [0, t_n - p^m \mathcal{T}] \cup [t_n - p^m \mathcal{T}, t_n - p^{m-1} \mathcal{T}] \cup \cdots [t_n - p^2 \mathcal{T}, t_n - p \mathcal{T}] \cup [t_n - p \mathcal{T}, t_n], \quad (3)$$

where $\mathcal{T} = \omega h, h \in \mathbb{R}^+, m, \omega, p \in \mathbb{N}$ and $p^m \mathcal{T} \leq t_n < p^{m+1} \mathcal{T}$. Denote $M_h = \{hn, n \in \mathbb{N}\}$ and $l_1, l_2 \in \mathbb{N}, l_1 > l_2$, then $M_{l_2 h} \supset M_{l_1 h}$.

3. Predictor-corrector schemes

The problem of determining $y(t)$ by means of the information of *initial value* y_0 , is called *initial value problem*. As the classic theory of ordinary differential equation, if a function $y(t)$ satisfies the initial value problem (1) pointwisely, then $y(t)$ is called the *solution of the fractional differential equation* (1). For the existence and uniqueness of the solutions of fractional differential equations, one can see (Podlubny, 1999). But the explicit formula of the solution $y(t)$ can't usually be obtained in spite of we can prove the existence of solution. The most

reasonable way is to use numerical methods, and the obtained solution is called the *numerical approximation of the solution of the differential equations* (1) and denoted by y_h in the following sections.

3.1 Numerical schemes

In this section, we show the predictor-corrector schemes of (1). Using the Laplace transform formula for the Caputo fractional derivative (Podlubny, 1999)

$$\mathcal{L}\{D_*^\alpha y(t)\} = s^\alpha Y(s) - \sum_{k=0}^{n-1} s^{\alpha-k-1} y^{(k)}(0), \quad n-1 < \alpha \leq n. \quad (4)$$

From (1), we have

$$s^\alpha Y(s) - \sum_{k=0}^{n-1} s^{\alpha-k-1} y^{(k)}(0) = F(s, Y(s)), \quad (5)$$

or

$$Y(s) = s^{-\alpha} F(s, Y(s)) + \sum_{k=0}^{n-1} s^{-k-1} y^{(k)}(0), \quad (6)$$

where $F(s, Y(s)) = \mathcal{L}(f(t, y(t)))$. Applying the inverse Laplace transform gives

$$y(t) = \sum_{k=0}^{[\alpha]-1} y_0^{(k)} \frac{t^k}{k!} + \frac{1}{\Gamma(\alpha)} \int_0^t (t-\tau)^{\alpha-1} f(\tau, y(\tau)) d\tau, \quad (7)$$

where the fact

$$\mathcal{L}\{J^\mu y(t)\} = \mathcal{L}\left\{\frac{1}{\Gamma(\mu)} \int_0^t \frac{y(\tau)}{(t-\tau)^{1-\mu}} d\tau\right\} = \mathcal{L}\left\{\frac{t^{\mu-1}}{\Gamma(\mu)} * y(t)\right\} = s^{-\mu} Y(s),$$

and

$$\mathcal{L}\{t^{\mu-1}\} = s^{-\mu} \Gamma(\mu).$$

are used. The approximation is based on the equivalent form of the Volterra integral equation (7). A fractional Adams-predictor-corrector approach was firstly developed by Diethelm et al (Diethelm et al., 2002b) to numerically solve the problem (7). Using the standard quadrature techniques for the integral in (7), denote $g(\tau) = f(\tau, y(\tau))$, the integral is replaced by the trapezoidal quadrature formula at point t_{n+1}

$$\int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} g(\tau) d\tau \approx \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_{n+1}(\tau) d\tau, \quad (8)$$

where \tilde{g}_{n+1} is the piecewise linear interpolation of g with nodes and knots chosen at $t_j, j = 0, 1, 2, \dots, n+1$. After some elementary calculations, the right hand side of (8) gives

$$\int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_{n+1}(\tau) d\tau = \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^{n+1} a_{j,n+1} g(t_j), \quad (9)$$

where the uniform mesh is used and h is the stepsize. And if we use the product rectangle rule, the right hand of (8) can be written as

$$\int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_{n+1}(\tau) d\tau = \sum_{j=0}^n b_{j,n+1} g(t_j), \quad (10)$$

where

$$a_{j,n+1} = \begin{cases} n^{\alpha+1} - (n-\alpha)(n+1)^\alpha, & \text{if } j=0, \\ (n-j+2)^{\alpha+1} - 2(n-j+1)^{\alpha+1} + (n-j)^{\alpha+1}, & \text{if } 1 \leq j \leq n, \\ 1, & \text{if } j=n+1 \end{cases}$$

and

$$b_{j,n+1} = \frac{h^\alpha}{\alpha} [(n+1-j)^\alpha - (n-j)^\alpha], \quad \text{if } 0 \leq j \leq n+1.$$

Then the predictor and corrector formulae for solving (7) are given, respectively, by

$$y_h^p(t_{n+1}) = \sum_{k=0}^{[\alpha]-1} \frac{t_{n+1}^k}{k!} y_0^{(k)} + \frac{1}{\Gamma(\alpha)} \sum_{j=0}^n b_{j,n+1} f(t_j, y_h(t_j)) \quad (11)$$

and

$$y_h(t_{n+1}) = \sum_{k=0}^{[\alpha]-1} \frac{t_{n+1}^k}{k!} y_0^{(k)} + \frac{h^\alpha}{\Gamma(2+\alpha)} f(t_{n+1}, y_h^p(t_{n+1})) + \frac{h^\alpha}{\Gamma(2+\alpha)} \sum_{j=0}^n a_{j,n+1} f(t_j, y_h(t_j)). \quad (12)$$

The approximation accuracy of the scheme (11)-(12) is $O(h^{\min\{2,1+\alpha\}})$ (Diethelm et al., 2004).

Now we make some improvements for the scheme (11)-(12). We modify the approximation of (8) as (Deng, 2007a)

$$\int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} g(\tau) d\tau \approx \int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_n(\tau) d\tau + \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} g(t_n) d\tau, \quad (13)$$

where \tilde{g}_n is the piecewise linear interpolation for g with nodes and knots chosen at $t_j, j = 0, 1, 2, \dots, n$. Then using the standard quadrature technique, the right hand of (13) can be recast as

$$\int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_n(\tau) d\tau + \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} g(t_n) d\tau = \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^n \tilde{b}_{j,n+1} g(t_j) \quad (14)$$

where

$$\tilde{b}_{j,n+1} = \begin{cases} a_{j,n+1}, & \text{if } 0 \leq j \leq n-1, \\ 2^{\alpha+1} - 1, & \text{if } j = n. \end{cases} \quad \text{if } n > 0, \\ b_{0,1} = \alpha + 1, & \text{if } n = 0. \end{cases}$$

Hence, this algorithm for the predictor step can be improved as (Deng, 2007b)

$$y_h^p(t_{n+1}) = \sum_{k=0}^{[\alpha]-1} \frac{t_{n+1}^k}{k!} y_0^{(k)} + \frac{h^\alpha}{\Gamma(2+\alpha)} \sum_{j=0}^n \tilde{b}_{j,n+1} f(t_j, y_h(t_j)), \quad (15)$$

The new predictor-corrector approach (15) and (12) has the numerical accuracy $O(h^{\min\{2,1+2\alpha\}})$ (the detailed analysis is left in Section 3.2). Obviously half of the

computational cost can be reduced, for $0 < \alpha \leq 1$, if we reformulate (15) and (12) as

$$y_h^P(t_{n+1}) = \begin{cases} y_0 + \frac{h^\alpha}{\Gamma(\alpha+1)} f(y_h(t_0), t_0), & \text{if } n = 0, \\ y_0 + \frac{h^\alpha}{\Gamma(\alpha+2)} \cdot (2^{\alpha+1} - 1) \cdot f(y_h(t_n), t_n) \\ + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^{n-1} a_{j,n+1} f(y_h(t_j), t_j), & \text{if } n \geq 1 \end{cases} \quad (16)$$

and

$$y_h(t_{n+1}) = \begin{cases} y_0 + \frac{h^\alpha}{\Gamma(\alpha+2)} \left(f(y_h^P(t_1), t_1) + \alpha \cdot f(y_h(t_0), t_0) \right), & \text{if } n = 0, \\ y_0 + \frac{h^\alpha}{\Gamma(\alpha+2)} \left(f(y_h^P(t_{n+1}), t_{n+1}) + (2^{\alpha+1} - 2) \cdot f(y_h(t_n), t_n) \right) \\ + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^{n-1} a_{j,n+1} f(y_h(t_j), t_j), & \text{if } n \geq 1. \end{cases} \quad (17)$$

The arithmetic complexity of the above two predictor-corrector schemes ((11)-(12), and (16)-(17)) is $O(h^{-2})$, where h is step size.

For further reducing the computational cost, we understand the short memory principle from a new viewpoint, and then go to design the predictor-corrector scheme (Deng, 2007b). For $\alpha \in (0, 1)$ and $\alpha \in (1, \infty)$, we rewrite (7) as, respectively,

$$y(t_{n+1}) = y(t_n) + \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \\ + \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau, \quad \alpha \in (0, 1) \quad (18)$$

and

$$y(t_{n+1}) = \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) + \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \\ + \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau, \quad \alpha \in (1, \infty). \quad (19)$$

By observation of (18) and (19), we can see that the non-local property of D_*^α induces the term

$$\frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau. \quad (20)$$

In fact, if $\alpha \in (0, 2)$ the integration kernel of (20) fades faster when the time history becomes longer, more concretely,

$$\begin{aligned}
 & \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau \\
 &= \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_0^{t_n} \left(\int_{t_n-\tau}^{t_{n+1}-\tau} z^{\alpha-2} dz \right) f(\tau, y(\tau)) d\tau \\
 &= \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_{n-1}}^{t_n} \left(\int_{t_n-\tau}^{t_{n+1}-\tau} z^{\alpha-2} dz \right) f(\tau, y(\tau)) d\tau \\
 &+ \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_{n-2}}^{t_{n-1}} \left(\int_{t_n-\tau}^{t_{n+1}-\tau} z^{\alpha-2} dz \right) f(\tau, y(\tau)) d\tau \\
 &+ \cdots + \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_1}^{t_2} \left(\int_{t_n-\tau}^{t_{n+1}-\tau} z^{\alpha-2} dz \right) f(\tau, y(\tau)) d\tau \\
 &+ \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_0}^{t_1} \left(\int_{t_n-\tau}^{t_{n+1}-\tau} z^{\alpha-2} dz \right) f(\tau, y(\tau)) d\tau \tag{21} \\
 &= \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_{n-1}}^{t_n} (z_1^*(\tau))^{\alpha-2} f(\tau, y(\tau)) d\tau + \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_{n-2}}^{t_{n-1}} (z_2^*(\tau))^{\alpha-2} f(\tau, y(\tau)) d\tau \\
 &+ \cdots + \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_1}^{t_2} (z_{n-1}^*(\tau))^{\alpha-2} f(\tau, y(\tau)) d\tau \\
 &+ \frac{1}{\Gamma(\alpha)(\alpha-1)} \int_{t_0}^{t_1} (z_n^*(\tau))^{\alpha-2} f(\tau, y(\tau)) d\tau,
 \end{aligned}$$

where $z_m^*(\tau) \in (t_{m-1}, t_{m+1})$, $m = 1, 2, \dots, n$. Obviously, we can see that the integration (20)'s kernel $(t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}$ decays (algebraically) by the order $2 - \alpha$ when $\alpha \in (0, 2)$, but in (Ford & Simpson, 2001) the integral kernel $(t_{n+1} - \tau)^{\alpha-1}$ decays with the order $1 - \alpha$ when $\alpha \in (0, 1)$. This is the main reason why we can extend the range of the *short memory principle* of fractional differential equations from $\alpha \in (0, 1)$ to $\alpha \in (0, 2)$. For the nested meshes defined by (3), we can take the step length h in the integral $[t_n - p\mathcal{T}, t_n]$ and in the subsequent intervals $[t_n - p^2\mathcal{T}, t_n - p\mathcal{T}]$, $[t_n - p^3\mathcal{T}, t_n - p^2\mathcal{T}]$, \dots , $[t_n - p^m\mathcal{T}, t_n - p^{m-1}\mathcal{T}]$, $[t_0, t_n - p^m\mathcal{T}]$, step lengths $ph, p^2h, \dots, p^{m-1}h, p^mh$ are used, respectively. Noting that $(t_n - p^m\mathcal{T}) - 0$ can't be divided by p^mh , so the integral in the interval $[0, l]$ ($l = (t_n - p^m\mathcal{T}) - \lfloor (t_n - p^m\mathcal{T}) / (p^mh) \rfloor \cdot (p^mh)$) is ignored, it does not destroy the computational accuracy in general. We will pay our attention to the numerical approximation by using *short memory principle* in the integration (20) in the following part.

With the similar approximation of (13), the product trapezoidal quadrature formula is applied to replace the integral of (19), where nodes $t_j, j = n, n+1$ are taken with respect to the weighted function $(t_{n+1} - \cdot)^{\alpha-1}$ for the first integral and nodes $t_j, j = 0, 1, \dots, n$ are used w.r.t. the weighted function $(t_{n+1} - \cdot)^{\alpha-1} - (t_n - \cdot)^{\alpha-1}$ for the second integral, and it yields

$$\begin{aligned}
 & \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \approx \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} \tilde{f}_{n+1}(\tau, y(\tau)) d\tau \\
 &= \frac{h^\alpha}{\alpha(\alpha+1)} (\alpha f(t_n, y(t_n)) + f(t_{n+1}, y(t_{n+1}))), \quad \alpha \in (1, \infty) \tag{22}
 \end{aligned}$$

and

$$\begin{aligned}
 & \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau \\
 & \approx \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) \tilde{f}_n(\tau, y(\tau)) d\tau \\
 & = \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y(t_j))
 \end{aligned} \tag{23}$$

where

$$\tilde{a}_{j,n} = \begin{cases} (n+1)^{\alpha+1}(\alpha-n) + n^\alpha(2n-\alpha-1) - (n-1)^{\alpha+1}, & \text{if } j=0, \\ (n-j+2)^{\alpha+1} - 3(n-j+1)^{\alpha+1} + 3(n-j)^{\alpha+1} - (n-j-1)^{\alpha+1}, & \text{if } 1 \leq j \leq n-1, \\ 2^{\alpha+1} - \alpha - 3, & \text{if } j=n. \end{cases} \tag{24}$$

For the first integral of (18) or (19), the product rectangle formula is used

$$\int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \approx \int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} f(t_n, y(t_n)) d\tau = \frac{h^\alpha}{\alpha} f(t_n, y(t_n)). \tag{25}$$

Combining (22)-(25), for $\alpha \in (1, 2)$, the new predictor-corrector approach gives

$$\begin{aligned}
 y_h^P(t_{n+1}) &= y_0^{(1)} \cdot h + y_h(t_n) + \frac{h^\alpha}{\Gamma(\alpha+1)} f(t_n, y_h(t_n)) \\
 &+ \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)), \quad \alpha \in (1, 2)
 \end{aligned} \tag{26}$$

and

$$\begin{aligned}
 y_h(t_{n+1}) &= y_0^{(1)} \cdot h + y_h(t_n) + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y_h(t_n)) \\
 &+ f(t_{n+1}, y_h^P(t_{n+1}))) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)), \quad \alpha \in (1, 2).
 \end{aligned} \tag{27}$$

For $\alpha \in (2, \infty)$, the predictor-corrector approach is

$$\begin{aligned}
 y_h^P(t_{n+1}) &= \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y_h(t_n) \\
 &+ \frac{h^\alpha}{\Gamma(\alpha+1)} f(t_n, y_h(t_n)) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)), \quad \alpha \in (2, \infty)
 \end{aligned} \tag{28}$$

and

$$\begin{aligned}
 y_h(t_{n+1}) &= \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y_h(t_n) + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y_h(t_n)) + \\
 &f(t_{n+1}, y_h^P(t_{n+1}))) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)), \quad \alpha \in (2, \infty).
 \end{aligned} \tag{29}$$

The predictor and corrector formulae based on the analytical formula (19) is fully described by (28) and (29) with the weighted $\tilde{a}_{j,n}$ defined by (24). It is apparent that the same term $\sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j))$ exists in both predictor (28) and corrector formulae (29), we just need to compute one times at each predictor-corrector iteration step.

In order to reduce the computational cost, in conjunction with the nested meshes memory principle (3), decompose the integral and still use the product trapezoidal quadrature formula at each subinterval but with different step lengths.

$$\begin{aligned} & \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau \\ & \approx \left(\int_{t_n - p\omega h}^{t_n} + \sum_{i=1}^{m-1} \int_{t_n - p^{i+1}\omega h}^{t_n - p^i\omega h} + \int_0^{t_n - p^m\omega h} \right) ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) \tilde{f}_n(\tau, y(\tau)) d\tau \\ & = \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=n-p\omega}^n b_{j,p^0,n} f(t_j, y(t_j)) \end{aligned} \quad (30)$$

$$\begin{aligned} & + \sum_{i=1}^{m-1} \frac{(p^i h)^\alpha}{\alpha(\alpha+1)} \left(\sum_{j=0}^{(p-1)\omega} b_{j,p^i,n} f(t_n - p^i(\omega + j)h, y(t_n - p^i(\omega + j)h)) \right) \\ & + \frac{(p^m h)^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^{\lceil n/p^m - \omega \rceil - 1} b_{j,p^m,n} f(t_n - p^m(\omega + j)h, y(t_n - p^m(\omega + j)h)), \end{aligned} \quad (31)$$

where

$$b_{j,p^0,n} = \begin{cases} (p\omega+1)^\alpha(\alpha-p\omega) + (p\omega)^\alpha(2p\omega-\alpha-1) - (p\omega-1)^{\alpha+1}, & \text{if } j = n - p\omega, \\ (n-j+2)^{\alpha+1} - 3(n-j+1)^{\alpha+1} + 3(n-j)^{\alpha+1} \\ - (n-j-1)^{\alpha+1}, & \text{if } n - p\omega + 1 \leq j \leq n-1, \\ 2^{\alpha+1} - \alpha - 3, & \text{if } j = n \end{cases}$$

and for $i = 1, 2, \dots, m$,

$$b_{j,p^i,n} = \begin{cases} -(1/p^i + \omega)^{\alpha+1} + \omega^{\alpha+1} + (1/p^i + \omega + 1)^{\alpha+1} \\ - (\omega + 1)^{\alpha+1} - ((1/p^i + \omega)^\alpha - \omega^\alpha)(\alpha + 1), & \text{if } j = 0, \\ (\omega + j - 1 + 1/p^i)^{\alpha+1} - (\omega + j - 1)^{\alpha+1} - 2(\omega + j + 1/p^i)^{\alpha+1} \\ + 2(\omega + j)^{\alpha+1} + (\omega + j + 1 + 1/p^i)^{\alpha+1} - (\omega + j + 1)^{\alpha+1}, & \text{if } 1 \leq j \leq (p-1)\omega - 1, \\ (p^i\omega - 1 + 1/p^i)^{\alpha+1} - (p^i\omega - 1)^{\alpha+1} - (p^i\omega + 1/p^i)^{\alpha+1} \\ + (p^i\omega)^{\alpha+1} + ((p^i\omega + 1/p^i)^\alpha - (p^i\omega)^\alpha)(\alpha + 1), & \text{if } j = (p-1)\omega. \end{cases}$$

Employing above analysis we obtain the following predictor-corrector algorithm

$$\begin{aligned} y_h^P(t_{n+1}) &= y_0^{(1)} \cdot h + y_h(t_n) + \frac{h^\alpha}{\Gamma(\alpha+1)} f(t_n, y_h(t_n)) + \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=n-p\omega}^n b_{j,p^0,n} f(t_j, y(t_j)) \\ &+ \sum_{i=1}^{m-1} \frac{(p^i h)^\alpha}{\alpha(\alpha+1)} \left(\sum_{j=0}^{(p-1)\omega} b_{j,p^i,n} f(t_n - p^i(\omega + j)h, y(t_n - p^i(\omega + j)h)) \right) \\ &+ \frac{(p^m h)^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^{\lceil n/p^m - \omega \rceil - 1} b_{j,p^m,n} f(t_n - p^m(\omega + j)h, y(t_n - p^m(\omega + j)h)) \end{aligned} \quad (32)$$

and

$$\begin{aligned}
 y_h(t_{n+1}) = & y_0^{(1)} \cdot h + y_h(t_n) + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y_h(t_n)) \\
 & + f(t_{n+1}, y_h^p(t_{n+1}))) + \frac{h^\alpha}{\alpha(\alpha+1)} \sum_{j=n-p\omega}^n b_{j,p^0,n} f(t_j, y(t_j)) \\
 & + \sum_{i=1}^{m-1} \frac{(p^i h)^\alpha}{\alpha(\alpha+1)} \left(\sum_{j=0}^{(p-1)\omega} b_{j,p^i,n} f(t_n - p^i(\omega+j)h, y(t_n - p^i(\omega+j)h)) \right) \\
 & + \frac{(p^m h)^\alpha}{\alpha(\alpha+1)} \sum_{j=0}^{[n/p^m - \omega] - 1} b_{j,p^m,n} f(t_n - p^m(\omega+j)h, y(t_n - p^m(\omega+j)h)). \quad (33)
 \end{aligned}$$

In this case, the nested meshes predictor-corrector algorithm has the computational cost of $O(h^{-1} \log(h^{-1}))$ for $\alpha \in (1, 2)$.

3.2 Error analysis and convergent order

In this section, we make the local truncation error and convergent order analysis for the improved predictor-corrector approaches (16)-(17), (26)-(29), and (32)-(33). First we present several lemmas which will be used later.

Lemma 1. (Diethelm et al., 2004) Suppose $g \in C^2[0, T]$,

$$\left| \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} g(\tau) d\tau - \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_{n+1}(\tau) d\tau \right| \leq C_\alpha h^2, \quad (34)$$

where C_α only depends on α .

Proof.

$$\begin{aligned}
 & \left| \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (g(\tau) - \tilde{g}_{n+1}(\tau)) d\tau \right| \\
 & \leq \frac{\|g''\|_\infty}{2} \sum_{j=1}^{n+1} \int_{t_{j-1}}^{t_j} (t_{n+1} - \tau)^{\alpha-1} (t_j - \tau)(\tau - t_{j-1}) d\tau \\
 & = \frac{\|g''\|_\infty h^{\alpha+2}}{2\alpha(\alpha+1)} \sum_{j=1}^{n+1} \left((n-j+2)^{\alpha+1} + (n-j+1)^{\alpha+1} + \frac{2}{\alpha+2} ((n-j+2)^{\alpha+2} - (n-j+1)^{\alpha+2}) \right) \\
 & = \frac{\|g''\|_\infty h^{\alpha+2}}{2\alpha(\alpha+1)} \sum_{j=1}^{n+1} \left((j+1)^{\alpha+1} + j^{\alpha+1} + \frac{2}{\alpha+2} (1 - (n+1)^{\alpha+2}) \right) \\
 & = -\frac{\|g''\|_\infty h^{\alpha+2}}{2\alpha(\alpha+1)} \left(2 \int_1^{n+1} \tau^{\alpha+1} d\tau - \sum_{j=1}^{n+1} ((j+1)^{\alpha+1} + j^{\alpha+1}) \right) \\
 & \leq \begin{cases} \frac{\|g''\|_\infty h^{\alpha+2}}{24} \sum_{j=1}^{n+1} j^{\alpha-1}, & \text{if } \alpha < 1, \\ \frac{\|g''\|_\infty h^{\alpha+2}}{24} \sum_{j=1}^{n+1} (j+1)^{\alpha-1}, & \text{if } \alpha \geq 1, \end{cases} \leq \begin{cases} \frac{\|g''\|_\infty h^{\alpha+2}}{24} \int_0^{n+1} \tau^{\alpha-1} d\tau, & \text{if } \alpha < 1, \\ \frac{\|g''\|_\infty h^{\alpha+2}}{24} \int_2^{n+2} \tau^{\alpha-1} d\tau, & \text{if } \alpha \geq 1, \end{cases} \\
 & \leq C_\alpha h^2. \quad (35)
 \end{aligned}$$

With the similar method, we can obtain the following lemma.

Lemma 2. Suppose $g \in C^2[0, T]$,

$$\left| \int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} g(\tau) d\tau - \int_0^{t_n} (t_{n+1} - \tau)^{\alpha-1} \tilde{g}_n(\tau) d\tau \right| \leq C_\alpha h^2, \quad (36)$$

where C_α only depends on α .

The error of the product rectangle rule is given as

Lemma 3. Suppose that $\partial f(\tau, y(\tau)) / \partial \tau \in C[0, t]$, for some suitable t , then we have

$$\left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (f(\tau, y(\tau)) - f(t_n, y(t_n))) d\tau \right| \leq C_\alpha h^{\alpha+1}, \quad (37)$$

where C_α only depends on α .

Proof.

$$\begin{aligned} & \left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (f(\tau, y(\tau)) - f(t_n, y(t_n))) d\tau \right| \\ & \leq \frac{\|\partial f(\tau, y(\tau)) / \partial \tau\|_\infty}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (\tau - t_n) d\tau \\ & = \frac{\|\partial f(\tau, y(\tau)) / \partial \tau\|_\infty}{\Gamma(\alpha)} \frac{1}{\alpha(\alpha+1)} h^{\alpha+1} \\ & \leq C_\alpha h^{\alpha+1} \quad \text{where} \quad C_\alpha = \frac{\|\partial f(\tau, y(\tau)) / \partial \tau\|_\infty}{\Gamma(\alpha+2)}. \end{aligned} \quad (38)$$

Lemma 4. Suppose that $\partial^2 f(\tau, y(\tau)) / \partial^2 \tau \in C[0, t]$, for some suitable t , then we have

$$\left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (f(\tau, y(\tau)) - \tilde{f}_{n+1}(\tau, y(\tau))) d\tau \right| \leq C_\alpha h^{\alpha+2}, \quad (39)$$

where C_α only depends on α .

Proof. According to the property of linear interpolation polynomials,

$$f(\tau, y(\tau)) - \tilde{f}_{n+1}(\tau, y(\tau)) = f[\tau, t_n, t_{n+1}] (\tau - t_n)(\tau - t_{n+1}), \quad (40)$$

where $f[\tau, t_n, t_{n+1}]$ is second divided differences. And using the fact

$$\begin{aligned} & \int_{t_j}^{t_{j+1}} (t_{n+1} - \tau)^{\alpha-1} (\tau - t_j)(\tau - t_{j+1}) d\tau \\ & = \int_{t_j}^{t_{j+1}} (t_{n+1} - \tau)^{\alpha-1} [(t_j - t_{n+1} + t_{n+1} - \tau)(t_{j+1} - t_{n+1} + t_{n+1} - \tau)] d\tau \\ & = \int_{t_j}^{t_{j+1}} [t_{n-j+1} t_{n-j} (t_{n+1} - \tau)^{\alpha-1} - (t_{n-j} + t_{n-j+1})(t_{n+1} - \tau)^\alpha + (t_{n+1} - \tau)^{\alpha+1}] d\tau \\ & = \frac{1}{\alpha(\alpha+1)} (t_{n-j+1}^{\alpha+1} t_{n-j} - t_{n-j}^{\alpha+1} t_{n-j+1}) + \frac{1}{(\alpha+1)(\alpha+2)} (t_{n-j}^{\alpha+2} - t_{n-j+1}^{\alpha+2}) \\ & = \frac{2}{\alpha(\alpha+1)(\alpha+2)} (t_{n-j+1}^{\alpha+2} - t_{n-j}^{\alpha+2}) - \frac{h}{\alpha(\alpha+1)} (t_{n-j+1}^{\alpha+1} + t_{n-j}^{\alpha+1}) \quad \text{for all } j \geq 0, \end{aligned} \quad (41)$$

we have

$$\begin{aligned}
 & \left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (f(\tau, y(\tau)) - \tilde{f}_{n+1}(\tau, y(\tau))) d\tau \right| \\
 &= \left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f[\tau, t_n, t_{n+1}] (\tau - t_n)(\tau - t_{n+1}) d\tau \right| \\
 &= \left| \frac{f[\xi, t_n, t_{n+1}]}{\Gamma(\alpha)} \right| \cdot \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (\tau - t_n)(\tau - t_{n+1}) d\tau \\
 &= \left| \frac{f''(\eta, y(\eta))}{2\Gamma(\alpha)} \right| \cdot \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (\tau - t_n)(\tau - t_{n+1}) d\tau \\
 &= \left| \frac{f''(\eta, y(\eta))}{2\Gamma(\alpha)} \right| \cdot \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)} \quad (\text{taking } j = n \text{ in (41)}) \\
 &\leq C_\alpha h^{\alpha+2} \quad \text{where } C_\alpha = \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)(\alpha+1)(\alpha+2)}. \tag{42}
 \end{aligned}$$

Here $\xi, \eta \in [t_n, t_{n+1}]$ and in the above equalities the second integral mean value theorem and the properties of second divided differences are used.

Lemma 5. Suppose that $\partial^2 f(\tau, y(\tau)) / \partial^2 \tau \in C[0, t]$, for some suitable t , then we have

$$\left| \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) (f(\tau, y(\tau)) - \tilde{f}_n(\tau, y(\tau))) d\tau \right| \leq C_\alpha h^{\min\{\alpha+2, 3\}}, \tag{43}$$

where C_α only depends on α .

Proof. The idea of this lemma's proof is similar to the above lemmas, namely

$$\begin{aligned}
 & \left| \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) (f(\tau, y(\tau)) - \tilde{f}_n(\tau, y(\tau))) d\tau \right| \\
 &\leq \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \sum_{j=0}^{n-1} \int_{t_j}^{t_{j+1}} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) (\tau - t_j)(\tau - t_{j+1}) d\tau \right| \\
 &\leq \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \sum_{j=0}^{n-1} \int_{t_j}^{t_{j+1}} (t_{n+1} - \tau)^{\alpha-1} (\tau - t_j)(\tau - t_{j+1}) d\tau \right. \\
 &\quad \left. - \int_{t_j}^{t_{j+1}} (t_n - \tau)^{\alpha-1} (\tau - t_j)(\tau - t_{j+1}) d\tau \right| \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \sum_{j=0}^{n-1} \left[\frac{2}{\alpha(\alpha+1)(\alpha+2)} (t_{n-j+1}^{\alpha+2} - t_{n-j}^{\alpha+2}) - \frac{h}{\alpha(\alpha+1)} (t_{n-j+1}^{\alpha+1} + t_{n-j}^{\alpha+1}) \right. \right. \\
 &\quad \left. \left. - \frac{2}{\alpha(\alpha+1)(\alpha+2)} (t_{n-j}^{\alpha+2} - t_{n-j-1}^{\alpha+2}) + \frac{h}{\alpha(\alpha+1)} (t_{n-j}^{\alpha+1} + t_{n-j-1}^{\alpha+1}) \right] \right| \quad (\text{using (41)}) \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \sum_{j=0}^{n-1} \left\{ \frac{-2(t_{n-j}^{\alpha+2} - t_{n-j+1}^{\alpha+2} - t_{n-j-1}^{\alpha+2})}{\alpha(\alpha+1)(\alpha+2)} - \frac{h}{\alpha(\alpha+1)} (t_{n-j+1}^{\alpha+1} - t_{n-j}^{\alpha+1}) \right\} \right| \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ \frac{-2(t_n^{\alpha+2} - t_{n+1}^{\alpha+2} - t_1^{\alpha+2})}{\alpha(\alpha+1)(\alpha+2)} - \frac{h}{\alpha(\alpha+1)} (t_{n+1}^{\alpha+1} + t_n^{\alpha+1} - t_1^{\alpha+1}) \right\} \right|
 \end{aligned}$$

$$\begin{aligned}
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ \frac{-2(t_n^{\alpha+2} - t_{n+1}^{\alpha+2})}{\alpha(\alpha+1)(\alpha+2)} - \frac{h}{\alpha(\alpha+1)}(t_{n+1}^{\alpha+1} + t_n^{\alpha+1}) + \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)} \right\} \right| \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ \frac{-h(t_{n+1}^{\alpha+1} + t_n^{\alpha+1} - 2(z^*)^{\alpha+1})}{\alpha(\alpha+1)(\alpha+2)} + \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)} \right\} \right| \quad (\text{mean value theorem}) \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ \frac{-h((t_{n+1}^{\alpha+1} - (z^*)^{\alpha+1}) - ((z^*)^{\alpha+1} - t_n^{\alpha+1}))}{\alpha(\alpha+1)} + \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)} \right\} \right| \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ \frac{-h^2((z^{**})^\alpha - (\tilde{z}^{**})^\alpha)}{\alpha} + \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)} \right\} \right| \quad (\text{mean value theorem}) \\
 &= \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| \left\{ -h^3((z^{***})^{\alpha-1} + \frac{h^{\alpha+2}}{(\alpha+1)(\alpha+2)}) \right\} \right| \quad (\text{mean value theorem}) \\
 &\leq C_\alpha \cdot h^{\min\{\alpha+2, 3\}}, \tag{44}
 \end{aligned}$$

where $z^* \in [t_n, t_{n+1}]$, $z^{**} \in [z^*, t_{n+1}] \subset [t_n, t_{n+1}]$, $\tilde{z}^{**} \in [t_n, z^*] \subset [t_n, t_{n+1}]$, $z^{***} \in [\tilde{z}^{**}, z^{**}] \subset [t_n, t_{n+1}]$ and

$$C_\alpha = \frac{\|f''(\eta, y(\eta))\|_\infty}{2\Gamma(\alpha)} \cdot \left| (z^{***})^{\alpha-1} - \frac{1}{(\alpha+1)(\alpha+2)} \right|.$$

Lemma 6. (Diethelm et al., 2004) Assume that the solution of the initial value problem satisfies

$$\left| \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} D_*^\alpha y(\tau) d\tau - \sum_{k=0}^{n+1} \tilde{b}_{j,n+1} D_*^\alpha y(t_j) \right| \leq C_1 t_{n+1}^{\gamma_1} h^{\delta_1} \tag{45}$$

and

$$\left| \int_0^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} D_*^\alpha y(\tau) d\tau - \sum_{k=0}^{n+1} a_{j,n+1} D_*^\alpha y(t_j) \right| \leq C_2 t_{n+1}^{\gamma_2} h^{\delta_2}, \tag{46}$$

with some $\gamma_1, \gamma_2 \geq 0$ and $\delta_1, \delta_2 \geq 0$. Then, for some suitably chosen $T \geq 0$, we have

$$\max_{0 \leq j \leq N} |y(t_j) - y_h(t_j)| = O(h^q), \tag{47}$$

with $q = \min\{\delta_1 + \alpha, \delta_2\}$ and $N = \lfloor T/h \rfloor$.

Theorem 1. For the fractional initial problem (1), if $D_*^\alpha y(t) \in C^2[0, T]$ for some suitable T , then the convergent order of our algorithm with the predictor and corrector formulae (16) and (17) gives $\max_{j=0,1,\dots,n+1} |y(t_j) - y_h(t_j)| = O(h^{\min\{2, 1+2\alpha\}})$.

Proof. Noting

$$\left| \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (g(\tau) - g(t_n)) d\tau \right| \leq \|g'\|_\infty \frac{h^{\alpha+1}}{\alpha(\alpha+1)}, \tag{48}$$

and applying lemmas 2, 4, 6, we have the above result.

Theorem 2. When $\alpha > 1$, if $\partial^2 f(\tau, y(\tau)) / \partial^2 \tau \in C[0, t]$ for some suitable t , then the local truncation error of our algorithm with the predictor and corrector formulae (26)-(27) ($\alpha \in (1, 2)$) and (28)-(29) ($\alpha \in (2, \infty)$) is $O(h^3)$, and the convergent order is 2, i.e., $\max_{j=0,1,\dots,n+1} |y(t_j) - y_h(t_j)| = O(h^2)$.

Proof. This proof will be used based on mathematical induction. In view of the given initial condition, the induction basis $j = 0$ is presupposed, it has convergent order 2. Now, assuming that the convergent order is 2 for $j = 0, 1, \dots, k, k \leq n$, we have the local truncation error

$$\begin{aligned}
 & \left| y(t_{n+1}) - \left\{ \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) \right. \right. \\
 & \quad \left. \left. + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y(t_n)) + f(t_{n+1}, y_h^P(t_{n+1}))) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 &= \left| \left\{ \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) + \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \right. \right. \\
 & \quad \left. \left. + \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau \right\} - \left\{ \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) \right. \right. \\
 & \quad \left. \left. + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y(t_n)) + f(t_{n+1}, y_h^P(t_{n+1}))) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 &= \left| \left\{ \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau - \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y(t_n)) + f(t_{n+1}, y(t_{n+1}))) \right\} \right. \\
 & \quad \left. + \frac{h^\alpha}{\Gamma(\alpha+2)} (f(t_{n+1}, y(t_{n+1})) - f(t_{n+1}, y_h^P(t_{n+1}))) \right. \\
 & \quad \left. + \left\{ \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau - \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y(t_j)) \right\} \right. \\
 & \quad \left. + \left\{ \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y(t_j)) - \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right|.
 \end{aligned}$$

Then we have

$$\begin{aligned}
 & \left| y(t_{n+1}) - \left\{ \sum_{k=1}^{[\alpha]-1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) \right. \right. \\
 & \quad \left. \left. + \frac{h^\alpha}{\Gamma(\alpha+2)} (\alpha f(t_n, y(t_n)) + f(t_{n+1}, y_h^P(t_{n+1}))) + \frac{h^\alpha}{\Gamma(\alpha+2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 & \leq C_1 h^{\alpha+2} + \frac{\alpha L}{\Gamma(\alpha+2)} h^{\alpha+\min\{\alpha+1,3\}} + \frac{\alpha L}{\Gamma(\alpha+2)} h^{\alpha+\min\{\alpha+2,3\}} + \left| \left(-\frac{1}{2} h^\alpha + (z_*)^{\alpha-1} h \right) \right| L h^2 \\
 & \leq C h^3,
 \end{aligned}$$

where $z_* \in (t_n, t_{n+1})$, Lemmas 4 and 5 in the above proof are used, and we also utilize the result $|y(t_{n+1}) - y_h^P(t_{n+1})| = O(h^{\min\{\alpha+1,3\}})$ which can be proved by using Lemmas 4 and 5

and the similar idea to above proof, its sketch proof is given as

$$\begin{aligned}
 & \left| y(t_{n+1}) - \left\{ \sum_{k=1}^{\lceil \alpha \rceil - 1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) \right. \right. \\
 & \quad \left. \left. + \frac{h^\alpha}{\Gamma(\alpha + 1)} f(t_n, y(t_n)) + \frac{h^\alpha}{\Gamma(\alpha + 2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 &= \left| \left\{ \sum_{k=1}^{\lceil \alpha \rceil - 1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) + \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau \right. \right. \\
 & \quad \left. \left. + \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau \right\} - \left\{ \sum_{k=1}^{\lceil \alpha \rceil - 1} \frac{y_0^{(k)}}{k!} (t_{n+1}^k - t_n^k) + y(t_n) \right. \right. \\
 & \quad \left. \left. + \frac{h^\alpha}{\Gamma(\alpha + 1)} f(t_n, y(t_n)) + \frac{h^\alpha}{\Gamma(\alpha + 2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 &= \left| \left\{ \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} f(\tau, y(\tau)) d\tau - \frac{h^\alpha}{\Gamma(\alpha + 2)} f(t_n, y(t_n)) \right\} \right. \\
 & \quad \left. + \left\{ \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau - \frac{h^\alpha}{\Gamma(\alpha + 2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right\} \right| \\
 &\leq \left| \frac{1}{\Gamma(\alpha)} \int_{t_n}^{t_{n+1}} (t_{n+1} - \tau)^{\alpha-1} (f(\tau, y(\tau)) - f(t_n, y(t_n))) d\tau \right| \\
 & \quad + \left| \frac{1}{\Gamma(\alpha)} \int_0^{t_n} ((t_{n+1} - \tau)^{\alpha-1} - (t_n - \tau)^{\alpha-1}) f(\tau, y(\tau)) d\tau - \frac{h^\alpha}{\Gamma(\alpha + 2)} \sum_{j=0}^n \tilde{a}_{j,n} f(t_j, y_h(t_j)) \right| \\
 &\leq \dots \leq Ch^{\min\{\alpha+1, 3\}}.
 \end{aligned}$$

We have proved that the local truncation error of our algorithm (26)-(27) and (28)-(29) is $O(h^3)$ when $\alpha > 1$, so the convergent order is 2.

Lemma 7. (Ford Simpson [6, Theorem 1]) *The nested mesh scheme preserves the order of the underlying quadrature rule on which it is based.*

Because of Theorem 2, Lemma 7, and the analysis in above section, we have

Theorem 3. *When $\alpha > 1$, if $\partial^2 f(\tau, y(\tau)) / \partial^2 \tau \in C[0, t]$ for some suitable t , then the local truncation error of our algorithm with the predictor and corrector formulae (32)-(33) ($\alpha \in (1, 2)$) is $O(h^3)$ and the convergent order is 2, i.e., $\max_{j=0,1,\dots,n+1} |y(t_j) - y_h(t_j)| = O(h^2)$.*

The comparison of the local truncation error, convergent order and arithmetic complexity for different predictor-corrector schemes are presented in the following table. So far, our convergence results are obtained under the smoothness assumptions of $D_*^\alpha y(t)$ and f , which obviously depend on the smoothness properties of the solution $y(t)$ (Deng, 2010).

4. Numerical results

In this section we present two numerical examples to illustrate the performance of our proposed predictor-corrector schemes. We show the order of convergence in the the absolute

Schemes	Local truncation error	Convergent order	Arithmetic complexity
(11),(12)	$O(h^3)$	$O(h^{\min\{2,1+\alpha\}})$	$O(h^{-2})$
(16),(17)	$O(h^3)$	$O(h^{\min\{2,1+2\alpha\}})$	$O(h^{-2})$
(26)-(29)	$O(h^3)$	$O(h^2)$	$O(h^{-2})$
(32),(33)	$O(h^3)$	$O(h^2)$	$O(h^{-1} \log(h^{-1}))$

Table 1. Comparison of different predictor-corrector schemes.

error. And the convergence order is measured by

$$\text{Order} = \log_2 \left(\frac{\text{error}(h)}{\text{error}(h/2)} \right)$$

where $\text{error}(h)$ is the absolute error $|y(t) - y_h(t)|$ with the step h .

Example 1. Consider the following fractional differential equation

$$D_*^\alpha y(t) = \frac{\Gamma(5)}{\Gamma(5-\alpha)} t^{4-\alpha} - y(t) + t^4, \quad \alpha \in (0,2), \tag{49}$$

with the initial conditions

$$y(0) = 0, \alpha \in (0,1), \tag{50}$$

or

$$y(0) = 0, y'(0) = 0, \alpha \in (1,2), \tag{51}$$

note that the exact solution to this problem is

$$y(t) = t^4. \tag{52}$$

The numerical results for the predictor-corrector scheme (16)-(17) at time $t = 1$ with different steps and different α are reported in Tables 2 and 3. Table 1 shows the numerical errors at time $t = 1$ between the exact solution and the numerical solution of the predictor-corrector schemes (16)-(17) for (49) with different $\alpha \in (0,1)$ for various step sizes. It is seen that the rate of convergence of the numerical results is of order $O(\tau^{\min\{2,1+2\alpha\}})$ for the predictor-corrector schemes (16)-(17). Tables 2 and 3 show the ratio of the error reduction as the grid is refined. The last row states the theoretical orders of convergence (abbreviated as TOC), which are the results we theoretically prove in the above theorems. From Tables 2 and 3, it can be noted that the numerical results are in excellent agreement with the theoretical ones given in Theorem 1.

Example 2. Now, consider the following fractional differential equation (Diethelm et al., 2004)

$$D_*^\alpha y(t) = \begin{cases} \frac{2}{\Gamma(3-\alpha)} t^{2-\alpha} - \frac{1}{\Gamma(2-\alpha)} t^{1-\alpha} - y(t) + t^2 - t, & \text{if } 0 < \alpha < 1, \\ \frac{2}{\Gamma(3-\alpha)} t^{2-\alpha} - y(t) + t^2 - t, & \text{if } \alpha \geq 1. \end{cases} \tag{53}$$

with the initial conditions

$$y(0) = 0, \alpha \in (0,1), \tag{54}$$

or

$$y(0) = 0, y'(0) = -1, \alpha \in (1,2), \tag{55}$$

the exact solution to this problem is

$$y(t) = t^2 - t. \tag{56}$$

h	$\alpha = 0.1$	Order	$\alpha = 0.5$	Order	$\alpha = 0.9$	Order

TOC		1.20		2.00		2.00

Table 4. Absolute errors and convergence orders for predictor-corrector schemes (16)-(17) at time $t = 1$ with different α .

p	\mathcal{T}	Computing value	Absolute errors	Relative error (%)
1	1	2448.8	1.2	0.0489
2	4	2465.6	15.6	0.6367
2	3	2466.0	16.0	0.6530
2	2	2432.7	18.0	0.7347
3	4	2467.2	17.2	0.7020
3	3	2467.0	17.0	0.6939
3	2	2466.1	16.1	0.6571
4	4	2469.3	19.3	0.7878
4	3	2469.1	19.1	0.7796
4	2	2467.0	17.0	0.6939

Table 5. Error behavior versus the variation of p and \mathcal{T} (the definition of p and \mathcal{T} are given in (3)) at time $t = 50$ with exact (analytical) value $y(50) = 2450$, fractional order $\alpha = 1.5$, step length $h = 1/80$.

and the errors of the improved predictor-corrector scheme (16)-(17) are improved significantly compared with the Tables 3 and 4 given in (Diethelm et al., 2004).

Table 5 shows the computing values, the absolute numerical errors, and the relative numerical errors by using the scheme (32) and (33) to compute Example 2 for different values of p and \mathcal{T} defined in (3). According to the numerical results we can see that the computing errors are generally acceptable in engineering when the computational cost is greatly minimized, especially the computing error is not sensitive to the value of p . On the other hand, this numerical example also illuminates that the algorithm is numerically stable.

5. Conclusions

We briefly review the numerical techniques for efficiently solving fractional ordinary differential equations. The possible improvements for the fractional predictor-corrector algorithm are presented. Even though the algorithm is designed for scalar fractional ordinary differential equation, it can be easily extended to the systems. In fact, based on this algorithm, we have simulated the dynamics of fractional systems (Deng, 2007c;d). In addition, the fractional predictor-corrector algorithm combining with the scheme of generating stochastic variables also works well for the stochastic fractional ordinary differential equations (Deng & Barkai, 2009).

Published online 23, March, 2012

Published in print edition March, 2012

This book demonstrates applications and case studies performed by experts for professionals and students in the field of technology, engineering, materials, decision making management and other industries in which mathematical modelling plays a role. Each chapter discusses an example and these are ranging from well-known standards to novelty applications. Models are developed and analysed in details, authors carefully consider the procedure for constructing a mathematical replacement of phenomenon under consideration. For most of the cases this leads to the partial differential equations, for the solution of which numerical methods are necessary to use. The term Model is mainly understood as an ensemble of equations which describe the variables and interrelations of a physical system or process. Developments in computer technology and related software have provided numerous tools of increasing power for specialists in mathematical modelling. One finds a variety of these used to obtain the numerical results of the book.
